**Blockchain success starts here**

Hundreds of successful client engagements. Dozens of networks producing tangible business results each day. The security of the IBM Cloud. Tools that slash activation time by 2/3rds. And ease-of-use to make any developer a blockchain developer. This is the IBM Blockchain Platform™, the complete blockchain for business experience. What will we solve together?

secure blockchain apps

**Blockchain Workbench >**

### What is a blockchain?

Blockchain is a transparent and verifiable system that will change the way people think about exchanging value and assets, enforcing contracts, and sharing data. The technology is a shared, secure ledger of transactions distributed among a network of computers, rather than resting with a single provider. Businesses are using blockchain as a common data layer to enable a new class of applications. Now, business processes and data can be shared across multiple organizations, which eliminates waste, reduces the risk of fraud, and creates new revenue streams.

**Harvard Business Review**

#### How Blockchain will Accelerate Business Performance and Power the Smart Economy

"When fully automated, blockchain can enforce consistency in execution, assist with dispute resolution, increase accountability, and deliver end-to-end transparency that can inform better

# HOW BITCOIN WORKS: MAINTAINING A LEDGER

From:	To:	\$\$\$
	Arvind	200
	Matt	200
....	....	....
Matt	Alex	50
Arvind	Jacob	20
Jacob	Georgios	100
....	....	....

Start simple.

Remove trust and scale up.

# PROBLEM #1: AUTHORIZING TRANSACTIONS

- What if someone (**Alex**) tries to move money to their account without the owner's (**Matt**) authorization?
- Fix: Digital Signatures!

From:	To:	\$\$\$
	Arvind	200
	Matt	200
....	....	....
Matt	Alex	50
Arvind	Jacob	20
Jacob	Georgios	100
....	....	....
<b>Matt</b>	<b>Alex</b>	1000
<b>Matt</b>	<b>Alex</b>	1000

# PROBLEM #1: AUTHORIZING TRANSACTIONS

From:	To:	\$\$\$	Signed
....	....	....	
....	....	....	
Alex	Georgios	100	<i>Alex's signature</i>
Matt	Alex	1000	<i>Matt's signature</i>
Matt	Alex	1000	
....	....	....	

# BASIC CRYPTOGRAPHY 1: HASH FUNCTIONS

- Input:
  - Any string of any size
- Output:
  - Fixed size output (say 256-bits)
- Property #0: Efficiently computable
  - In fact linear time
- Property #1: Collision resistant
  - Basically impossible (computationally) to find a collision: inputs  $x$  and  $y$  that map to the same output  $H(x) = H(y)$
  - Note: collisions exist. We ask that they are hard to find.

# BASIC CRYPTOGRAPHY 1: HASH FUNCTIONS

- Property #2: Hiding
  - If a value  $x$  is chosen from a sufficiently big set, then given  $H(x)$  it is hard to find  $x$
  - Fancier: If a secret value  $r$  is chosen from a probability distribution with high min-entropy, then given  $H(x||r)$  it is infeasible to find  $x$
- Why a big set?

# BASIC CRYPTOGRAPHY 1: HASH FUNCTIONS

- Example application: Commitment
- We want to run a sealed bid auction without a centralized authority
- How do you commit to a value?
  1. Publish  $H(\textit{nonce} || \textit{value})$ 
    - *nonce* = large random number
  2. After you see everyone's  $H(\cdot)$ , publish *value* and *nonce*
- Everyone can verify whether someone lied!

# BASIC CRYPTOGRAPHY 2: SIGNATURES

- Problem: I want to cryptographically sign a document
  - Only I should be able to sign it (**unforgeability**), but everyone should be able to check that my signature is valid
- Solution: Public key cryptography
- I have has a private key  $p_1$ 
  - Only I know  $p_1$
- I have a public key  $p_2$ 
  - Everyone knows  $p_2$
- Functionality:
  - $Sign(doc, p_1) = \text{signature}$
  - $Verify(signature, p_2, doc) \in \{Valid, Invalid\}$

# RSA FOR ENCODING/DECODING

- Pick two large primes  $p$  and  $q$
- $N = p \cdot q$
- Choose  $e$  relatively prime to  $(p - 1)(q - 1)$
- Compute  $d = e^{-1} \bmod (p - 1)(q - 1)$
- Public key:  $N$  and  $e$
- Private key:  $d$
- $Encode(x) = x^e \bmod N$
- $Decode(x) = x^d \bmod N$

# RSA FOR SIGNATURES

- Pick two large primes  $p$  and  $q$
- $N = p \cdot q$
- Choose  $e$  relatively prime to  $(p - 1)(q - 1)$
- Compute  $d = e^{-1} \bmod (p - 1)(q - 1)$
- Public key:  $N$  and  $e$
- Private key:  $d$
- $Sign(x) = x^d \bmod N$
- $Verify(x) = x^e \bmod N$

# PROBLEM #1: AUTHORIZING TRANSACTIONS

From:	To:	\$\$\$	Signed
....	....	....	
....	....	....	
Alex	Georgios	100	Alex's signature
Matt	Alex	1000	Matt's signature
Matt	Alex	1000	
....	....	....	

Sign( 

Matt	Alex	1000
------	------	------

 , Matt's private key ) = Matt's signature

Verify( signature, Matt's public key, 

Matt	Alex	1000
------	------	------

 ) ∈ { Valid, Not Valid }

# PROBLEM #2: SPENDING MONEY YOU DON'T HAVE

What if someone (**Georgios**) tries to spend money they don't have?

From:	To:	\$\$\$	Signed
....	....	....	
....	....	....	
<b>Georgios</b>	Matt	1000	Georgios' sign.
<b>Georgios</b>	Jacob	1000	Georgios' sign.
<b>Georgios</b>	Arvind	1000	Georgios' sign.
....	....	....	

# PROBLEM #2: SPENDING MONEY YOU DON'T HAVE

- Fix: Scan past transactions and check flow of money.

	From:	To:	\$\$\$	Input	Signed
#123	Alex	Georgios	100	#51	Alex's sign.
....	....	....	....	....	
#256	Matt	Georgios	900	#100	Matt's sign.
....	....	....	....	....	....
#1100	Georgios	Arvind	1000	#123, #256	Georgios' sign.
....	....	....	....		

Make sure this money wasn't spent in this interval

# PROBLEM #3: DECENTRALIZE

## With a trusted center

- Center maintains a single ledger
- Center adds transactions as they come.
- Center checks validity.
- Center makes sure no one double spends.
- Center adds new people to the system.

# PROBLEM #3: DECENTRALIZE

## Without a trusted center

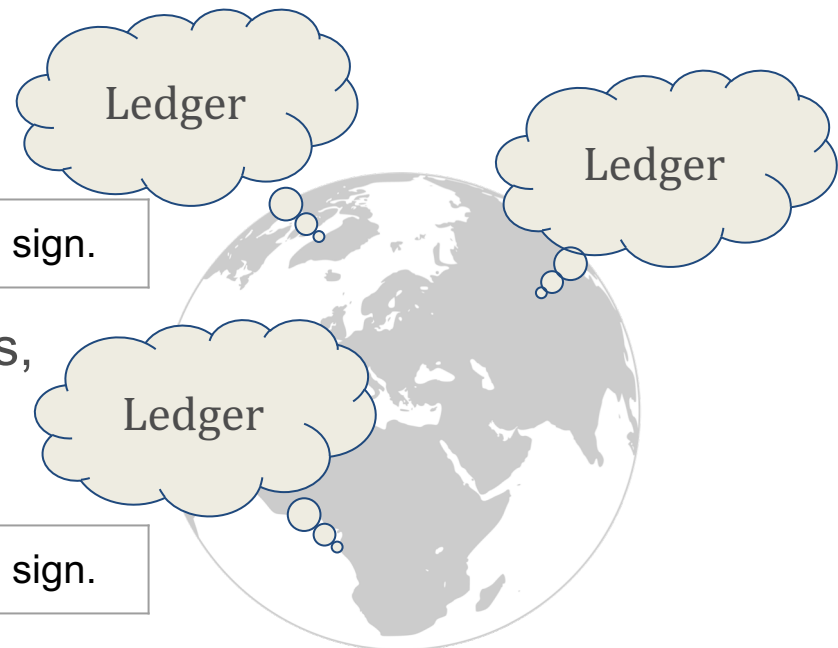

- Who maintains the ledger?
- Who has authority over which transactions are valid?
- How do we prevent double spending?

Scenario: Alex wants to buy a car from Matt.

Alex	Matt	10000\$	Input = #127	Alex's sign.
------	------	---------	--------------	--------------

As soon as Matt gives Alex the keys, broadcast:

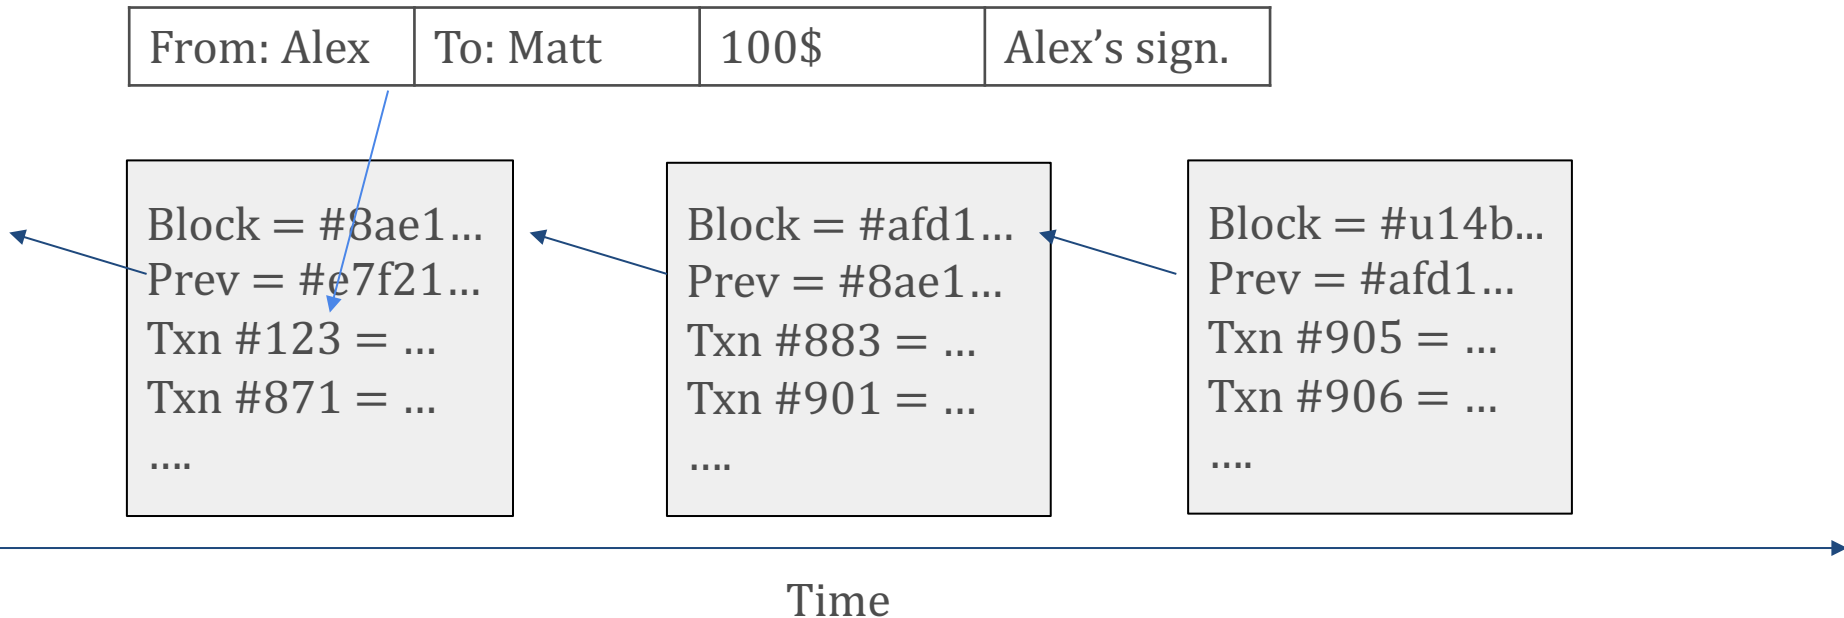

Alex	Jacob	10000\$	Input = #127	Alex's sign.
------	-------	---------	--------------	--------------

# BLOCKCHAIN

- Cryptocurrency maintains a directed graph of **blocks**.
- A block contains confirmed/valid transactions
- If a transaction is not in a block then by definition it is not valid/confirmed.

# HOW ARE BLOCKS MADE?

- Blocks are made by **miners**
- Miners validate new transactions and add them to the blockchain
- Problem: which miner gets to make the next block?
  - Pick a participant uniformly at random
  - The environment is permissionless!
  - Users can create as many accounts (“Sybils”) as they want!
  - Effectively a race to ~~the bottom~~ see who can create more Sybils.

# PROOF OF WORK

Miners compete to solve a “crypto puzzle”

**Goal:** The cryptographic hash of the entire text of a block plus an additional number (the **nonce**) must be in a certain range

$$\text{SHA256} \left( \begin{array}{l} \text{Block} = \dots \\ \text{Txn \#905} = \dots \\ \text{Txn \#906} = \dots \\ \dots \\ \text{nonce} \end{array} \right) = 0x\underbrace{0000000000000000\dots00}_{\text{A bunch of zeros}}b39d9ca51f07fef3429ae15.$$

**Idea:** Solving the puzzle first is proportional to your **computational power!**

# HOW ARE BLOCKS MADE?

- Blocks are made by **miners**
- Miners validate new transactions and add them to the blockchain
- ~~Problem: which miner gets to make the next block?~~
- The first miner to solve the crypto puzzle broadcasts their block. It's easy to check that it is a valid block
- Problem: why would miners for all this?

# PROOF OF WORK

For doing this intensive work, block creators are rewarded in two ways:

- Block reward: add a special transaction giving the miner a certain number of (new) bitcoins. Currently 12.5 Bitcoin per block.
- Transaction fees: “tips” from the participants of the transaction to the miner, if the transaction is included in the new block.

These rewards are “real” only if the block is in the “true” history, i.e. this block is an ancestor to future blocks.

# DIFFICULTY ADJUSTMENT

- The number of leading zeros gets adjusted every 2016 blocks so that a block gets created every ~10 minutes
- The block reward is scheduled to be halved every 4 years
  - Eventually all rewards will come from transaction fees
  - Very different incentives

# BRANCHES

- The network so far:

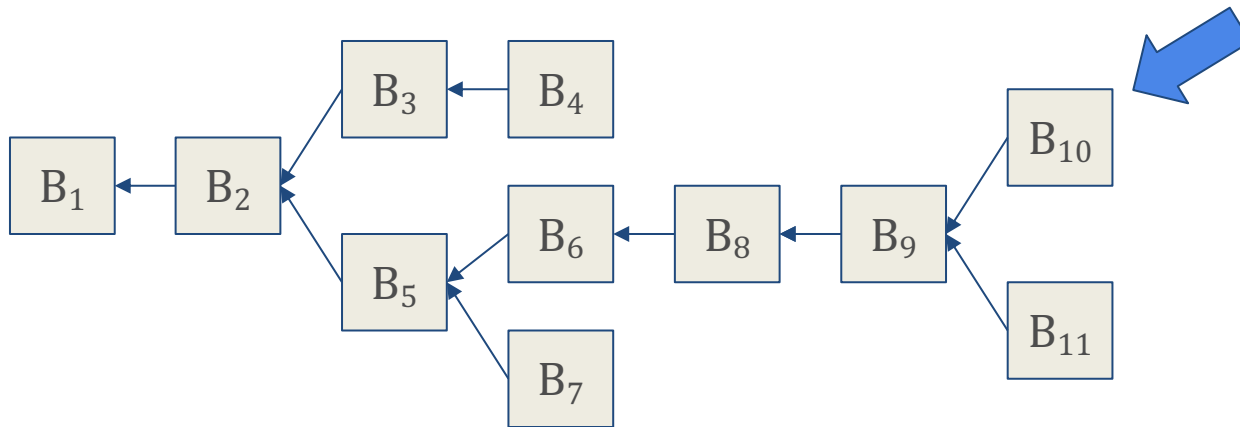

- Which block should a miner try to extend?

**Longest chain**

# BRANCHES

- The network so far:

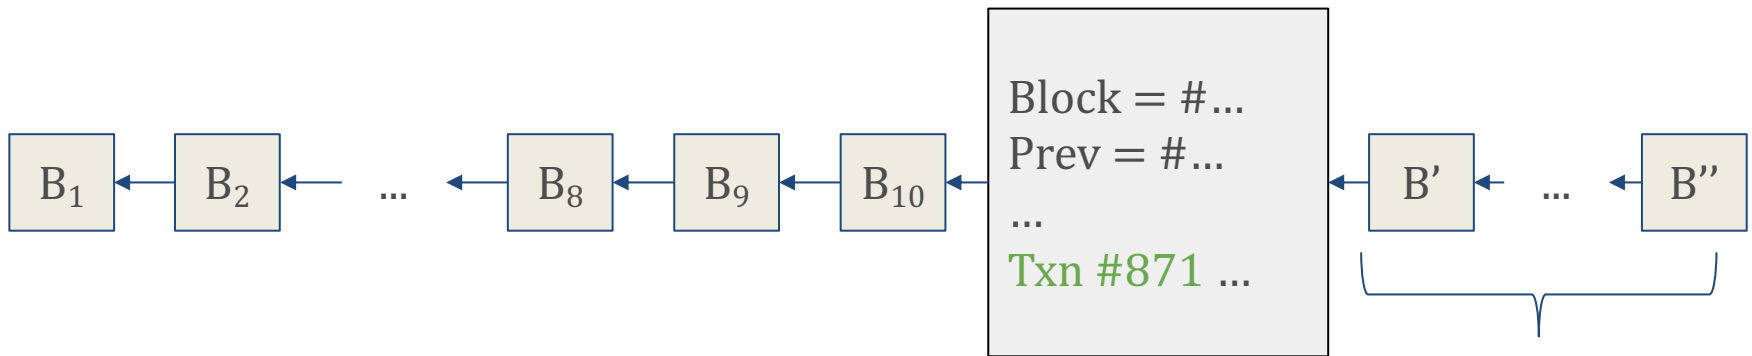

- More than one block is solved at the same time (plus natural network delays)
- Which block should a miner try to extend?

**The first one you hear about**

# PROOF OF WORK: RECAP

View of someone who wants to make a transaction

Txn=#871	Georgios	Arvind	1		....

# POLL

1. Choose which block to try to extend
2. Forge transactions
3. Choose which transactions to include
4. Change the contents of published blocks
5. Win disproportionately often

## Poll

What can a miner do?

1. 1,2 and 3
2. 1 and 3

3. 2, 4 and 5
4. 1 and 2

# MINING POOLS

- Solo miner is very unlikely to find a new block, even with dedicated hardware
  - There are ~1.5 millions blocks a year
  - 12.5 bitcoins ~ 65000\$
  - If you have 0.0000001% of the global mining power your expected annual income is 65000\$
  - Too much variance!
- Miners create **pools**
  - If a miner in a pool mines a new block, the block reward gets split between all miners in the pool, proportional to their mining power

# MINING POOLS

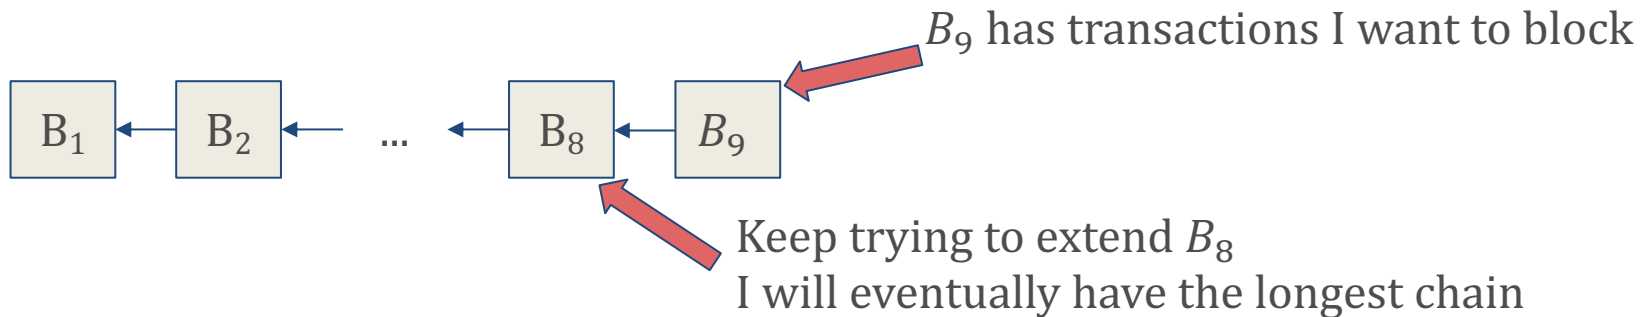

- How can you distribute rewards fairly?
- A valid block must hash to a number with (say) 70 leading zeros
- Typically, a (nonce that gives a) block with 65 leading zeros is useless
- Show it to the rest of the mining pool
- “Proof of effort”
  - Miners that are actively trying to find valid blocks and have a lot of computational power will produce these “partial” solutions often
- Distribute rewards proportional to partial solutions

# IS BITCOIN SECURE?

- Can an adversary take control of Bitcoin?
- Say adversary has 51% of the computational power
- Can they steal money?
  - No!
  - If you add unsigned transactions sending money to yourself, even if you have the longest chain, the rest of the network will ignore your blocks

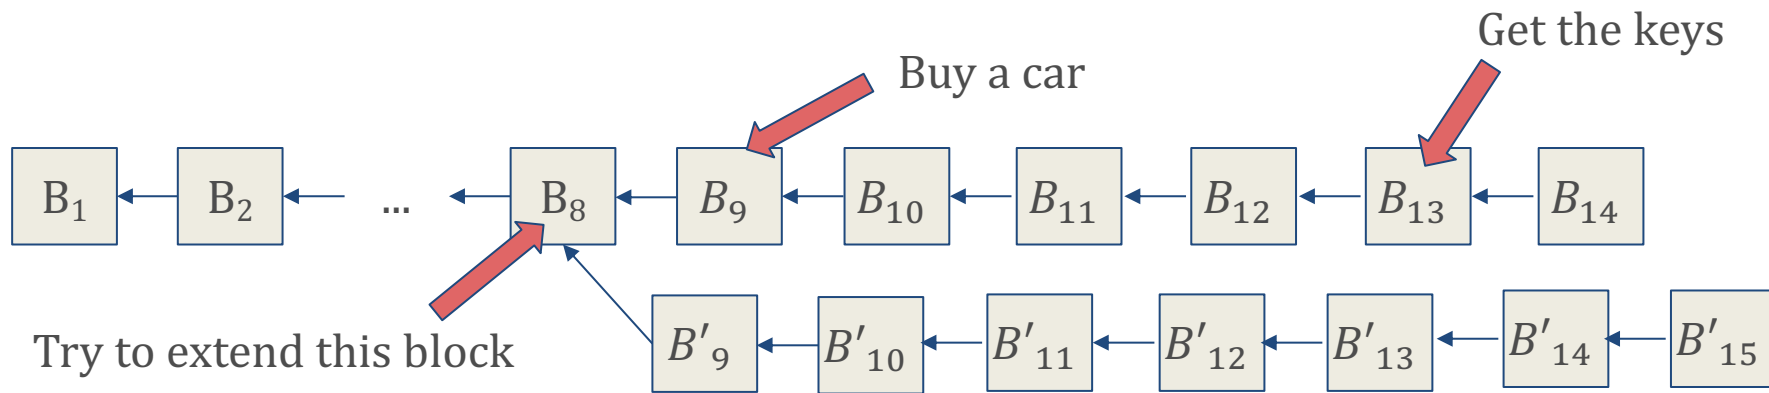

# IS BITCOIN SECURE?

- Can they effectively remove someone from the network?
  - Yes!
  - If I don't like some participant, I can simply never include any of their transactions (anonymity makes this hard of course)
  - If someone mines before me and includes these transactions, I can ignore their block and mine on top of the old one

# IS BITCOIN SECURE?

- Can they “double spend”?
  - Spend the same bit coin twice

- Since you have more computational power than the rest of the network, you'll eventually catch up

# IS BITCOIN SECURE?

- Bitcoin community: “Why would anyone do this?”
  - “If someone had 51% of all the mining power, they can make a bunch of money by mining normally”
  - “If they do these tricks, they’ll make Bitcoin not trusted, and therefore hurt their own investment”
- Arguing about incentives is precisely what we do in mechanism design!
  - Vs research in security, where you worry about trolls
